**PRIORITY
 DOCUMENT**
 SUBMITTED OR TRANSMITTED IN
 COMPLIANCE WITH RULE 17.1(a) OR (b)

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

Notes

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 08459 500505.
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay please contact the Patent Office.

1 **Compositions and Uses Thereof**

2

3 **Field of the Invention**

4

5 The present invention relates to methods of
6 controlling serum glucose levels in mammals. In
7 particular it relates to methods for the prevention
8 of severe fluctuations in glucose levels and the use
9 of these methods in the treatment of diseases
10 characterised by hypoglycaemia, such as glycogen
11 storage disease (GSD), clinical conditions where a
12 slow release of energy in the form of glucose may be
13 required (e.g. diabetes) and for sports and fitness
14 type products where a slow release of energy is
15 desirable.

16

17 **Background to the Invention**

18

19 The release of energy from foods and food products
20 is a complex process. It depends on the composition,
21 structure, extent of modification and volume of the
22 food. Apart from this, it is also variable between

1 individuals and reflects many different factors
2 which probably include a combination of age, level
3 of fitness, rate of gastric emptying and
4 peristalsis, sex, size, state of health etc. Energy
5 may be derived from different food sources, for
6 example, carbohydrates, lipids and proteins, alcohol
7 etc. In many animals, including man, energy is
8 stored as fat (adipose tissue) and provides a
9 reserve when food is limiting. There is a more
10 readily available form of energy, however, where a
11 glucose polymer (glycogen) is stored in muscles and
12 the liver and can be rapidly mobilised when
13 required. The formation and storage of glycogen is a
14 synchronised enzymatic process which is controlled
15 in part by insulin which promotes the formation of
16 glycogen from the glucose precursors (Figure 1).
17 Glucose deposition and glycogen catabolism is co-
18 ordinated in man to maintain blood glucose at
19 $\sim 4.5 \text{ mmol l}^{-1}$.

20

21 *Glycogen storage disease*

22

23 In the normal human, the anabolism and catabolism of
24 glycogen is normally co-ordinated and regulated. The
25 deposition of glycogen is promoted by insulin whilst
26 the hydrolysis of glycogen and conversion to glucose
27 is promoted by adrenaline (especially muscle) and
28 glucagons (especially liver).

29

30 In glycogen storage disease (GSD) there is an
31 inherited defect with respect to the deposition or
32 hydrolysis of glycogen

1 (<http://www.agsd.org.uk/home/information.asp>;
2 http://agsdus.org/body_what_is_1.html) and
3 consequently the concentration of blood glucose.
4 Figure 1 outlines the principles of glycogen
5 metabolism.

6
7 The most common types of glycogen storage disease
8 are:

9
10 In Type I (Von Gierke Disease) individuals suffer
11 from a lack of glucose-6-phosphatase activity ('h'
12 in Figure 1) and hence cannot generate glucose from
13 glycogen. Consequently they need to be tube fed to
14 maintain blood glucose.

15 In Type II (Pompe's Disease) individuals suffer
16 from a lack of α -glucosidase activity ('i' in Figure
17 1). Infants often die of this form very young.

18 In Type III (Cori's Disease) individuals suffer
19 from a lack of debranching enzyme activity ('i' in
20 Figure 1). Treatment usually consists of a high
21 protein diet.

22 In Type IV (Anderson's Disease) individuals
23 suffer from a lack of branching enzyme activity ('e'
24 in Figure 1). Liver transplantation is the only
25 viable therapy.

26 In Type V (McArdle's Disease) individuals suffer
27 from a lack of muscle phosphorylase activity ('f' in
28 Figure 1). Extensive exercise should be avoided.

29 In Type VI (Her's Disease) individuals suffer
30 from a lack of liver phosphorylase activity ('f' in
31 Figure 1). There is a male X- chromosome link.

1 In Type VII (Tarui's Disease) individuals suffer
2 from a lack of muscle phosphofructokinase activity.
3 Extensive exercise should be avoided.

4 In Type IX individuals suffer from a lack of
5 liver phosphorylase activity ('f' in Figure 1).
6 There is a male X- chromosome link and it is
7 comparable to type VI.

8
9 Low blood glucose can be treated by the slow
10 administration of glucose (oral or intra-venous), or
11 from starch hydrolysates (e.g. maltose, dextrans
12 etc.) or from native starch where glucose is
13 liberated as a consequence of digestion. In practice
14 'corn-starch', which is normal maize starch, is used
15 to treat glycogen storage disease (especially during
16 sleep) due to availability and to lack of a superior
17 alternative in terms of digestive response. The
18 starch must be slowly digested and not converted to
19 glucose rapidly or excreted with little hydrolysis..
20 In other clinical conditions (such as diabetes
21 mellitus) there is also the need to supply glucose
22 slowly and from a non-sugar based matrix (e.g.
23 cakes, biscuits, sweets etc.). This can, therefore,
24 also be achieved by starch (hydrolysis in the gut)
25 and is important for night time regimes where
26 glucose is essential in the blood but within a
27 controlled form.

28
29 The advantages and disadvantages of feeding glucose,
30 maltodextrins or maize starch for clinical nutrition
31 with a perceived optimal substrate are defined in
32 Table 1.

5

1

2 Table 1. Release profile of glucose based substrates
 3 in the gut of man with perceived optimised product
 4 in this respect

5

Entry to body	Glucose	Maltodextrin	Normal maize ('corn') starch	
Intravenous	Used extensively in medicine. Would need to be pumped constantly for GSD and diabetes clinical maintenance.	Too high molecular weight	Inappropriat e in view of size, composition and structure	Appropriate in view of size, composition and structure
Oral - small intestine	Rapidly absorbed (1.5 hours)	Rapidly absorbed (1.5 hours)	Glucose released within 4 hours	Glucose released over 7.5 hours (to provide overnight release)
Oral - large intestine	Not applicable	Not applicable	Possibly mostly digested with small amount of fermentable substrate	Minimal fermentable substrate to avoid loss of energy and fermentation

6

7 *Slow release of energy*

8

9 Apart for the clinical conditions described above,
 10 athletes require sustained release of energy. There

1 are many products on the market which release energy
 2 based on sugars or maltodextrins. These include
 3 products presented in Table 2. However, sugars and
 4 dextrins are absorbed very rapidly and these
 5 products must be consumed regularly to maintain the
 6 required body loading of the energy.

7
 8 Table 2. Energy based products currently found on
 9 the market.

10

Product	Carbohydrate, % of product	Carbohydrates used as energy source
Accelerade	7.75	Fructose, maltodextrin and sucrose
Allsport	9.00	High fructose syrup
Cytomax	6.00	High fructose syrup and maltodextrin
Enervit G	7.60	Fructose, glucose, maltodextrin and sucrose
Extran thirstquencher	5.00	Fructose and maltodextrin
G Push	7.50	Fructose, galactose and maltodextrin
Gatorade	6.00	Fructose, glucose and sucrose
GU20	5.70	Fructose and maltodextrin
Powerade	8.00	High fructose syrup and glucose polymers [sic]
Revenge Sport	7.00	Fructose, glucose and maltodextrin

11 (adapted from [www.accelerade.com/accelerade-](http://www.accelerade.com/accelerade-comparison-results.asp)
 12 [comparison-results.asp](http://www.accelerade.com/accelerade-comparison-results.asp))

1

2

3 *Slow energy release nutritional formulations*

4

5 As mentioned above, slow release products for sports
6 nutrition tend to be pouched relying on glucose or
7 maltodextrin to supply the energy. These actually
8 are absorbed quickly as they are either readily
9 absorbed (e.g. glucose) or converted to glucose
10 (e.g. maltodextrins, probably within 60 minutes
11 maximum).

12

13 On the other hand, glycogen storage disease (certain
14 treatable forms, see above) management requires that
15 patients receive a slow release of glucose overnight
16 (for example). Native starch is provided for this
17 purpose where: the initial liberation phase of
18 glucose is not too rapid (see figures below);
19 glucose is released at as constant a rate as
20 possible which must not be too slow or too fast and;
21 the production of lactate (anaerobic respiration) is
22 minimised. Certain starches are to be avoided as
23 they exhibit only limited hydrolysis in the native
24 form (e.g. potato).

25

26 Hence, the extent and rate of starch digestion are
27 important parameters with respect to glucose release
28 from the ingested α -glucan. Regulation in terms of
29 these parameters reflect the state of the starch and
30 the rate at which the energy source travels through
31 the gut. A balance in terms of energy release is

1 required which can be controlled by the energy
2 source and the transit time.

3

4 Osmolality is also an important feature with respect
5 to carbohydrate usage. Sugar solutions exert a high
6 osmotic pressure compared to polysaccharides due to
7 the number of moles in solution.

8

9 The viscosity of the consumed material will also
10 affect the capacity for it to be hydrolysed and to
11 permit associated compounds to come into contact
12 with the mucosal surface. This is a very important
13 issue with respect to product development regarding
14 potential energy sources.

15

16 Glycaemic Index (GI) is also an important
17 determinant of energy availability from foods and
18 more especially α -glucans. In this context, white
19 bread has a GI of 1 which is the same as pure
20 glucose and represents one hundred percent
21 availability of the α -glucan fraction (or 1 on a
22 scale from 0 to 1).

23

24 *Gastric emptying*

25

26 As mentioned above, the rate and extent of gastric
27 emptying will in part regulate the transit time of
28 food materials through the gut. It is established
29 that high volumes - low energy promote gastric
30 emptying whereas low volumes - high energy restrict
31 gastric emptying. Lipids and proteins are valuable

1 aids with respect to restricting emptying of the
2 stomach.

3
4 Glycogen storage disease and diabetes are
5 classically managed by feeding 'cornstarch' which is
6 normal maize starch (Kaufman, 2002). Sometimes,
7 proportions of carbohydrates are utilised which
8 provide rapid (e.g. sugar), medium (e.g. gelatinised
9 starch) and slow ('cornstarch') digestion and hence
10 glucose appearance in the blood (Wilbert, 1998).
11 Sugar combinations with or without maltodextrins or
12 'glucose polymers' are often employed in 'energy
13 drinks' (including rehydration drinks) and often
14 with other components like salts, protein, fatty
15 acids, glycerol, minerals, flavouring etc. (Gawen,
16 1981; Tauder et al, 1986; Burling et al, 1989;
17 Gordeladze, 1997; Paul and Ashmead, 1993 and 1994;
18 Vinci et al, 1993; Fischer et al, 1994; Simone,
19 1995; Gordeladze, 1997; King, 1998; Kurppa, 1998;
20 Cooper et al, 2001; Portman, 2002). The
21 maltodextrins/ glucose polymers are used to slow
22 energy availability (compared to sugars) and exert
23 less osmotic pressure.

24
25 Brynolf et al (1999) describe the production of an
26 acid modified starch with a molecular weight of
27 15,000 to 10M produced by classical acid hydrolysis
28 of starch to be used as an energy source prior to
29 physical activity. Lapré et al (1996) have
30 discussed the option of coating food with non-starch
31 polysaccharides (cation gelling) to reduce the
32 glycaemic response of carbohydrate containing foods.

1
2 However, although currently available starch
3 preparations used in the treatment of conditions
4 such as GSD have prolonged glucose release profiles
5 compared to glucose and maltodextrin based products,
6 the time period over which the products enable serum
7 glucose levels to be maintained within an acceptable
8 range is relatively short. Thus, at present, using
9 conventional oral preparations, patients susceptible
10 to hypoglycaemic episodes must ingest such glucose
11 sources at intervals of no longer than 4 hours.
12 Although this may be acceptable during daytime, the
13 need for repeated feeding is very inconvenient at
14 nighttime. The patient thus must either awake or be
15 wakened overnight to feed or, alternatively, sleep
16 with a nasogastric tube in place to provide a
17 constant source of glucose.

18

19 Accordingly, there is a great need for alternative
20 means of maintaining serum glucose levels within
21 safe ranges over a longer period of time than that
22 afforded by the conventional treatments.

23

24 Summary of the Invention

25

26 The present inventors, after considerable work, have
27 surprisingly discovered that semi-crystalline waxy
28 starches afford significantly prolonged glucose
29 release in the human GI tract compared to normal or
30 high amylose semi-crystalline starches as
31 conventionally used in preparations for slow energy

1 release.

2

3 Accordingly, in a first aspect, the present
4 invention provides a method of controlling serum
5 glucose levels in an individual said method
6 including the step of administering to said
7 individual a therapeutic food composition comprising
8 a waxy starch.

9

10 In a second aspect, the invention provides a method
11 of treating or preventing hypoglycaemia in an
12 individual said method including the step of
13 administering to said individual a therapeutic food
14 composition comprising a waxy starch.

15

16 According to a third aspect, the invention provides
17 a method of treating an individual susceptible to
18 hypoglycaemic episodes to prevent or decrease night-
19 time hypoglycaemic episode(s), said method including
20 the step of administering to said individual a
21 therapeutic food composition comprising a waxy
22 starch.

23

24 As described herein, the inventors have found that
25 waxy starches provide prolonged glucose release when
26 ingested.

27

28 Moreover, as well as discovering that such semi-
29 crystalline starches provide advantageous slow
30 glucose release, the inventors have unexpectedly
31 found that the time period over which glucose may be
32 released from starches and thus the time period over

1 which serum glucose levels may be maintained in
2 patients without the need for further doses of food
3 compositions can be markedly increased by
4 hydrothermal treatment of starches for use in the
5 invention. Indeed, as demonstrated in the Examples
6 below, the time period over which serum glucose
7 levels may be maintained in patients without the
8 need for further doses of food compositions may be
9 prolonged by use of such hydrothermally treated
10 starches (for example heat moisture treated
11 starches) to more than six hours, indeed typically
12 more than 7 hours. Thus, the use of such starches
13 (or indeed other hydrothermally treated starches) in
14 the methods of the invention enables a patient
15 susceptible to night-time hypoglycaemic episodes to
16 sleep for a substantially normal duration i.e. more
17 than 6 hour, preferably more than 7 hours without
18 the need for nasogastric feeding or further food
19 doses throughout the night.

20
21 Accordingly, in preferred embodiments of the
22 invention, the starch is hydrothermally treated
23 (HTT) waxy starch. Preferably said hydrothermally
24 treated waxy starch is heat-moisture treated (HMT)
25 waxy starch.

26
27 However, as well as finding that hydrothermal
28 treatment has very advantageous effects on waxy
29 starches, the inventors have also shown that
30 hydrothermal treatment also improves and prolongs
31 the glucose release profile of non-waxy starches.

32

1 Accordingly, in a fourth independent aspect of the
2 present invention, there is provided a method of
3 controlling serum glucose levels in an individual
4 said method including the step of administering to
5 said individual a therapeutic food composition
6 comprising a hydrothermally treated starch.

7
8 In a fifth aspect, the invention provides a method
9 of treating or preventing hypoglycaemia in an
10 individual said method including the step of
11 administering to said individual a therapeutic food
12 composition comprising a hydrothermally treated
13 starch.

14
15 According to a sixth aspect, the invention provides
16 a method of treating an individual susceptible to
17 hypoglycaemic episodes to prevent or decrease night-
18 time hypoglycaemic episode, said method including
19 the step of administering to said individual a
20 therapeutic food composition comprising
21 hydrothermally treated starch.

22
23 In the fourth , fifth and sixth aspects of the
24 invention, any suitable hydrothermally treated
25 starch may be used. Said hydrothermally treated
26 starch may be starch which has been heat moisture
27 treated or starch which has been subjected to
28 annealing treatment In preferred embodiments the
29 hydrothermally treated starch is heat moisture
30 treated starch.

31

1 In preferred embodiments of the invention, starch of
2 and for use in the invention is a "waxy starch".

3
4 Waxy starches for use in any aspect of the present
5 invention may be any starch having an amylopectin
6 content of at least 70%, preferably at least 80%,
7 more preferably at least 85%, even more preferably
8 at least 90%, yet more preferably at least 95%, most
9 preferably at least 98% amylopectin. Such waxy
10 starches may be cereal or non-cereal waxy starches.
11 Preferably, said waxy starch is a waxy cereal
12 starch, for example waxy maize starch.

13
14 Preferably, the starch of and for use in the
15 invention should have a granular size in the range
16 10 to 35 μ m, more preferably in the range 15 to 30 μ m.

17
18 Preferably the starch used in the invention enables
19 a blood glucose concentration of greater than 3.0
20 mmol l⁻¹ at 300 min post administration.

21
22 In preferred embodiments, the therapeutic food
23 composition is such that it, in use, its
24 administration results in a maximum blood glucose
25 concentration of no greater than 9 mmol l⁻¹.

26
27 In particularly preferred embodiments, the starch,
28 in use, enables a blood glucose concentration of
29 greater than 3.0 mmol l⁻¹ at 300 min post
30 administration, but does not cause a peak in blood
31 glucose concentration of any greater than 9.0 mmol
32 l⁻¹.

1
2 Preferably therapeutic food compositions of and for
3 use in the method of the present invention comprise
4 per unit dose greater than 50g, preferably greater
5 than 60g , for example more than 70g, even more
6 preferably greater than 80g, most preferably at
7 least 90g of the starch.

8
9 In a seventh aspect of the invention, there is
10 provided the use of a starch in the preparation of a
11 therapeutic foodstuff for the treatment of
12 hypoglycaemia, wherein said starch is a waxy and/or
13 hydrothermally treated starch.

14
15 Also provided by the invention is the use of starch
16 in the preparation of a therapeutic foodstuff for
17 the treatment or prevention of nighttime
18 hypoglycaemic episode, wherein said starch is a waxy
19 and/or hydrothermally treated starch.

20
21 Further provided by the invention is a therapeutic
22 foodstuff comprising a starch, wherein said starch
23 is a waxy and/or hydrothermally treated starch.

24
25 Therapeutic foodstuffs and food compositions of and
26 for use in the invention may be provided in kit
27 form. Accordingly, in a eighth aspect, the
28 invention provides a therapeutic food kit, said food
29 kit comprising:
30 a) a therapeutic food composition comprising starch,
31 wherein said starch is a waxy and/or hydrothermally
32 treated starch; and

16

1 b) instructions for ingesting said therapeutic food
2 composition.

3

4 Preferred features of each aspect of the invention
5 are as for each of the other aspects mutatis
6 mutandis.

7

8 Detailed description

9

10 As described above, the present inventors have
11 discovered that existing treatments for conditions
12 characterised by hypoglycaemic episodes may be
13 improved and/or supplemented by the use of waxy
14 starches as sources of α -glucan, thus enabling
15 significant improvement to control over the rate of
16 glucose formation and appearance in the blood
17 mammals. Such starches significantly out perform the
18 conventionally used 'corn starch' (native maize
19 starch) in terms of duration of glucose release due
20 to amylase hydrolysis in the small intestine.

21

22 Moreover, the inventors have shown that the glucose
23 release profile may be further dramatically
24 prolonged by modifications to the optimised starch
25 e.g. by hydrothermal treatment for example, by heat
26 moisture treatment. Indeed, hydrothermal treatment
27 also provides considerable improvement in
28 conventional non-waxy starches. Thus, the invention
29 also extends to the methods of the first, second and
30 third aspect of the invention, wherein the waxy
31 starch is substituted by any hydrothermally treated
32 starch, preferably heat moisture treated starch

17

1 (whether waxy or non-waxy) .

2

3 *Starches*

4

5 Starches are produced by plants as roughly spherical
6 granules ranging in diameter from <5 to >50 μ m.

7 Depending on source they contain ~11-17% moisture,

8 ~82-88% α -glucan, <~1.5% lipid and <~0.6% protein.

9 The α -glucan comprises two types of molecules:

10 amylose and amylopectin. The former is an

11 essentially linear molecule comprising about 99% α -

12 (1-4) and about 1% α -(1-6) bonds with a molecular

13 weight of ~500,000. Amylopectin is much bigger than

14 amylose with a molecular weight of a few million and

15 is heavily branched with ~95% α -(1-4) and ~5% α -(1-

16 6) bonds. The exterior chains of amylopectin

17 associate together as double helices which

18 themselves register together to form crystalline

19 laminates. These crystalline laminates are ...

20 interspersed with amorphous material comprising non-

21 crystalline (branched regions) of amylopectin plus

22 amylose. The amylose may form inclusion complexes in

23 cereal starches with lipids causing the presence of

24 two forms of the molecule: lipid complexed and lipid

25 free.

26

27 In normal starches, amylopectin is the 'seat' of

28 crystallinity. Waxy starches have a greater

29 proportion of crystallinity due to the higher

30 amylopectin content. High amylose starches contain

1 both amylopectin and amylose generated crystalline
2 material.

3

4 Starches containing <~20% amylose (80% amylopectin)
5 are commonly referred to as 'waxy', ~20-40% are
6 commonly referred to as 'normal' and ~>40% are
7 commonly referred to as high amylose or amylo-
8 starches. Normal maize and wheat starches are, for
9 example, ~30% amylose.

10

11 The semi-crystalline native starch granules are
12 insoluble and largely indigestible by man's
13 digestive enzymes. The control of native starch
14 digestion in man is not well understood although it
15 does not provide a major nutritional focus as most
16 starches are processed prior to cooking. Processing
17 of starch incorporates cooking in water which
18 disrupts the crystalline regions and 'gelatinises'
19 the starch. Gelatinised starches are very digestible
20 because of their amorphous nature by amylases and
21 related enzymes in the small intestine of man.
22 Native and resistant starches (below), although in
23 part digested in the small intestine, are fermented
24 in the colon. Products of carbohydrate fermentation
25 in the colon include short chain fatty acids (SCFAs)
26 and gasses like carbon dioxide, hydrogen and
27 methane.

28

29 Resistant starch takes a number of forms and simply
30 resists hydrolysis by enzymes synthesised in the
31 small intestine of man. This includes: small food
32 particles entrapping starch; native starch;

1 recrystallised (retrograded) starch and; chemically
2 modified starch.

3
4 If starches are hydrolysed (typically chemically
5 with acids or enzymatically with α -amylase and
6 amyloglucosidase) smaller molecules called
7 'dextrins' are generated. Products may be as small
8 as the smallest possible monosaccharide glucose or
9 be slightly hydrolysed but still polymeric. Glucose
10 syrups are made from starch hydrolysis and contain
11 variable proportions of sugars and dextrins
12 depending on the nature and extent of conversion.
13 The extent of conversion is usually defined as
14 dextrose equivalence (DE) which equates reducing
15 power of the hydrolysate to that of pure dextrose
16 (glucose).

17
18 Maltodextrins are DP20 or less, GRAS quality,
19 tasteless and very soluble. They are easily
20 digestible and are used in energy drinks because of
21 their solubility and reportedly relatively slow
22 digestibility compared to glucose (which is simply
23 absorbed). The difference in rate of glucose
24 appearance in the blood as a consequence of drinking
25 glucose or maltodextrin solutions is relatively
26 small (e.g. ~45minutes) because of the extent of
27 conversion of the maltodextrin.

28
29 In the present invention, any suitable semi-
30 crystalline or crystalline starch may be used. In
31 preferred embodiments, the starch of and for use in
32 the invention is a waxy starch.

1

2 The starch may be a naturally produced starch or may
3 be synthetically produced using any suitable method
4 e.g. plant breeding or biotechnological methods
5 (including transgenic technology etc.).

6

7 Preferred native starches are waxy with an average
8 diameter of around 15-35µm.

9

10

11 Hydrothermally Treated Starch

12

13 As discussed above and shown in the examples below,
14 the inventors have found that particularly good
15 results are obtained when using hydrothermally
16 treated starch.

17

18 Two main methods are currently used for the
19 hydrothermal treatment of starch: heat-moisture
20 treatment (high temperature, low moisture) and
21 annealing (high moisture, low temperature).

22

23 Heat Moisture Treated Starch (HMT Starch)

24

25 Heat and moisture treated starch is typically
26 produced by exposing moist starch (e.g. 15-30%
27 moisture) to temperatures of e.g. 95°C to 130° for
28 periods up to 30 hours (typically 16-24). These
29 ranges do not exclude other heat-moisture profiles.
30 For example, HMT starch for use in the invention may
31 be produced by thermally treating starch in a sealed
32 container under the following conditions: 20%

1 moisture and 105°C for 16 hours. The treated starch
2 may then be cooled to room temperature, air-dried
3 and then passed through 300um sieve.

4
5 Such heat moisture treatment results in a number of
6 significant property changes to starches. The extent
7 of the effect varies with the type of starch but in
8 general the effects are:

- 9
10 • increased gelatinisation temperature
11 • reduced water absorption and swelling power
12 • changed X-ray diffraction pattern
13 • increased enzyme susceptibility

14
15 As described herein, although heat moisture
16 treatment results in starches having increased
17 susceptibility to enzymatic degradation, the
18 inventors have surprisingly shown that when used in
19 methods of the invention, heat moisture treated
20 starches provide significantly greater prolongation
21 of the time period over which serum glucose levels
22 are maintained compared to the corresponding non
23 heat moisture treated starches.

24
25 **Annealing Treatment of Starch**

26
27 In certain embodiments of the invention the starch
28 of and for use in the invention is annealing treated
29 starch. Any suitable annealing treated starch may
30 be used.

31

1 Annealing is a process in which starch granules are
2 treated for a relatively long time in excess amounts
3 of water at a temperature slightly higher than room
4 temperature. Typically, annealing of starch
5 involves incubation of starch granules in water
6 (>40% w/w), for 1 hour to 10 days at a temperature
7 between the glass transition and the gelatinisation
8 temperature. Preferred annealing conditions are less
9 than 10°C below the onset of gelatinisation
10 temperature, in excess water for up to 7 days.

11

12 Treatment/Therapy

13

14 "Treatment" (which, unless the context demands
15 otherwise, is used interchangeably with "therapy",
16 includes any regime that can benefit a human or non-
17 human animal. The treatment may be in respect of an
18 existing condition or may be prophylactic
19 (preventative treatment). Treatment may include
20 curative, alleviation or prophylactic effects.

21

22 Food Compositions

23

24 The invention extends to a therapeutic food
25 composition for the treatment of diseases
26 characterised by hypoglycaemic episodes, wherein
27 said composition comprises a semi-crystalline
28 starch.

29

30 The therapeutic food compositions of and for use in
31 the present invention may consist solely of said
32 starches or preferably may comprise further

1 additives. Such additives may contribute merely to
2 the palatability of the composition, e.g.
3 flavourings, or may contribute significant calorific
4 value, for example, sugars with a more rapid release
5 profile than the starches, or lipids. These
6 compounds may be incorporated to slow gastric
7 emptying and facilitate the effect (e.g. amino
8 acids, lipids etc.).

9
10 The therapeutic food composition can take a variety
11 of forms, for example as a food, a food supplement,
12 a liquid, an emulsion or mixture thereof.
13 Preferably, it is prepared as a ready to eat
14 foodstuff, for example as a snackbar, a baked
15 product, pasta or drink.

16
17 Alternatively, the therapeutic food composition may
18 be administered as a pharmaceutical composition,
19 which will generally comprise a suitable
20 pharmaceutical excipient, diluent or carrier
21 selected dependent on the intended route of
22 administration.

23
24 Some suitable routes of administration include (but
25 are not limited to) oral, rectal or parenteral
26 (including subcutaneous, intramuscular, intravenous,
27 intradermal) administration.

28
29 For intravenous injection the active ingredient will
30 be in the form of a parenterally acceptable aqueous
31 solution which is pyrogen-free and has suitable pH,
32 isotonicity and stability. Those of relevant skill

1 in the art are well able to prepare suitable
2 solutions using, for example, isotonic vehicles such
3 as Sodium Chloride Injection, Ringer's Injection,
4 Lactated Ringer's Injection. Preservatives,
5 stabilisers, buffers, antioxidants and/or other
6 additives may be included, as required.

7
8 However, the composition is preferably for
9 administration orally. Pharmaceutical compositions
10 for oral administration may be in tablet, capsule,
11 powder or liquid form. A tablet may comprise a
12 solid carrier such as gelatin or an adjuvant.
13 Liquid pharmaceutical compositions generally
14 comprise a liquid carrier such as water, petroleum,
15 animal or vegetable oils, mineral oil or synthetic
16 oil. Physiological saline solution, dextrose or
17 other saccharide solution or glycols such as
18 ethylene glycol, propylene glycol or polyethylene
19 glycol may be included.

20
21 Examples of the techniques and protocols mentioned
22 above and other techniques and protocols which may
23 be used in accordance with the invention can be
24 found in Remington's Pharmaceutical Sciences, 16th
25 edition, Oslo, A. (ed), 1980.

26

27 Dose

28

29 The therapeutic food compositions of and for use in
30 the invention are preferably administered to an
31 individual in a "therapeutically effective amount",
32 this being sufficient to show benefit to the

1 individual. The actual amount administered, and
2 rate and time-course of administration, will depend
3 on the nature and severity of what is being treated.
4 Prescription of treatment, e.g. decisions on dosage
5 etc, is ultimately within the responsibility and at
6 the discretion of general practitioners and other
7 medical doctors, and typically takes account of the
8 disorder to be treated, the condition of the
9 individual patient, the site of delivery, the method
10 of administration and other factors known to
11 practitioners.

12
13 The optimal dose can be determined by physicians
14 based on a number of parameters including, for
15 example, age, sex, weight, severity of the condition
16 being treated, the active ingredient being
17 administered and the route of administration.

18
19
20 The invention will now be described further in the
21 following non-limiting examples. Reference is made
22 to the accompanying drawings in which:

23
24 Figure 1 shows schematically glucose and glycogen
25 metabolism reactions.

26
27 Figure 2 shows a comparison of the hydrolysis
28 profile of native starches using the Karkalas et al
29 (1992) procedure;

30

1 Figure 3 shows blood glucose level after consumption
2 of native starches;
3
4 Figure 4 shows a comparison of the blood lactate
5 level after consumption of native starches;
6
7 Figure 5 shows a comparison of blood glucose after
8 consumption of two native starches (wheat and waxy
9 maize) with added pregelatinised (maize) starch;
10
11 Figure 6 shows a comparison of the blood lactate
12 level after consumption of two native starches
13 (wheat and waxy maize) with added pregelatinised
14 (maize) starch;
15
16 Figure 7 shows a comparison of blood glucose after
17 consumption starch (native waxy maize and soluble)
18 encapsulated with pectin and alginate.
19

21 consumption of starch (native waxy maize and
22 soluble) encapsulated with pectin or alginate.
23
24 Figure 9 shows a comparison of blood glucose after
25 consumption of starch (native waxy maize, soluble)
26 encapsulated with lipid.
27
28 Figure 10 shows a comparison of blood glucose after
29 consumption of heat-moisture treated waxy maize
30 starch, waxy maize and normal maize starch.
31

1 Figure 11 shows a comparison of blood glucose after
2 consumption of heat-moisture treated waxy maize
3 starch, waxy maize and normal maize starch.

4
5 Figure 12 shows a comparison of digestibility of
6 native and heat-moisture treated waxy maize starches

7
8
9 **Example 1: In vitro hydrolysis**

10
11 Common native starches (barley, maize, potato, rice
12 and wheat) were evaluated using the Karkalas et al
13 (1992) (in vitro) method to identify their amylase
14 hydrolysis profile and potential for slow release of
15 energy in individuals. These data are presented in
16 Figure 2.

17
18 As can be seen from Figure 2 that rice starch has a
19 fast energy release profile initially followed by a
20 much slower process. In contrast, potato and high
21 amylose starches show great resistance towards
22 amylase hydrolysis and are nearly untouched by the
23 enzyme. Starches from normal maize, waxy maize and
24 wheat show continuous slow release energy profile.
25 These data provide the basis for an in vitro
26 selection of the most appropriate starch for this
27 purpose (as discussed later). Note that they do not
28 define the rate or extent of hydrolysis in the
29 actual gut but provide a means of ordering the rate
30 of extent of hydrolysis based on the in vitro
31 system.

32

1 **Example 2: Digestion of native starches**

2

3 Under clinical supervision, individuals suffering
4 from GSD were fed 60g samples of native starches
5 dispersed in semi-skimmed milk. The amount of blood
6 glucose and lactate were monitored and are presented
7 in Figures 3 and 4. Native potato starch was not
8 consumed in view of its resistance to digestion (and
9 cause of potential colonic disturbance accordingly).

10

11 These data show that waxy rice starch released
12 glucose very quickly where the highest (too high)
13 initial glucose peak (8.7 mmol l^{-1}) at 1 hour post
14 ingestion was obtained. The blood glucose level then
15 dropped to 3 mmol l^{-1} within 4.5 hours (270 minutes).
16 Normal rice showed a much lower initial glucose peak
17 with a longer release profile corresponding to
18 3.2 mmol l^{-1} within 5 hours (300 minutes) but less
19 glucose released in the time course of the
20 experiment compared to the waxy rice starch. High
21 amylose starch too extensively restricted glucose
22 release (although this could be moderated by
23 physical/ chemical/ enzymatic or biotechnological
24 modification). The normal maize starch ('corn
25 starch') exhibited a low glucose peak 1 hour
26 (6.6 mmol l^{-1}) after ingestion with an extended release
27 of 2.9 mmol l^{-1} after 300 minutes. The waxy maize
28 starch showed the optimal release profile with less
29 than 7 mmol l^{-1} blood glucose 1 hour post ingestion, a
30 significant glucose release profile for up to 6
31 hours (330 minutes) which dropped to 2.9 mmol l^{-1} at
32 this point.

1
2 Lactate in the blood also reflected the starch
3 consumed (Figure 4). The high amylose maize starch
4 provided the least lactate response (highest
5 lactate) as it was little digested (Figure 3). The
6 greatest reduction in lactate was achieved by the
7 waxy maize starch and in common with the previous
8 data promotes its potential use for GSD and similar
9 conditions requiring slow release of energy.

10
11 Based on these data, there is clearly a granule size
12 and compositional effect that regulates native
13 starch hydrolysis to glucose in the gut. There is a
14 balance between choosing a starch for therapy based
15 on the 1 hour glucose peak, duration of release and
16 the amount (integrated area) of glucose release with
17 time. The preferred starch for the purpose is,
18 therefore:

19
20 Highly crystalline (semi-crystalline) with waxy
21 starches providing the most appropriate crystalline
22 (amylopectin) matrices for this purpose.

23
24 Reasonably large granules without exceeding the
25 digestive capacity. Rice starches (~5µm diameter on
26 average) are too small. Maize starch granules are
27 preferred (~20-25µm diameter on average).

28
29 It is recognised that the cereal starches contain
30 lipid and that other starches may be more
31 appropriate in terms of size and composition.
32 However, in view of the lack of digestibility and

1 potential dangers of eating large granules (which
2 may cause colonic lesions) it is proposed that
3 granules in excess of $\sim 40\mu\text{m}$ diameter are not
4 consumed for this purpose.

5

6 **Example 3: Digestion of native starches in the**
7 **presence of a pre-gelatinised starch thickener**

8

9 Under clinical supervision, individuals suffering
10 from GSD were fed 50g samples of two native starches
11 (wheat or waxy maize) containing 54g of either
12 starch and 6g pregelatinised maize starch (National
13 B37, National Starch & Chemical) dispersed in cold
14 semi-skimmed milk. The amount of blood glucose and
15 lactate were monitored and are presented in Figures
16 5 and 6.

17

18 These data show that even in the presence of
19 amorphous (pre-gelatinised) starch the waxy maize
20 starch resists digestion (Figure 5) more than the
21 wheat starch, which contains a bi-modal distribution
22 of small ($\sim 10\mu\text{m}$ average diameter) and large ($\sim 25\mu\text{m}$
23 average diameter) granules but with similar
24 composition (amylose, lipid, moisture and protein).
25 This is reflected in a lower blood lactate (even
26 though the patients started with a higher lactate
27 content when presented with the waxy maize starch
28 (as shown in Figure 6). The importance of this work
29 is that it shows that even if the waxy starch is
30 mixed with other materials that have the capacity to
31 provide a quicker glucose response it can still
32 provide a slow release function.

1
2 **Example 4: Digestion of native starches in the**
3 **presence of non-starch polysaccharides**
4

5 Native waxy maize starch (Amioca Powder T, National
6 Starch) was encapsulated in soluble starch (Crystal
7 Tex 626, National Starch) and pectin (LM-104AS-FS,
8 CPKelco) or alginic acid (Manugel GMB, Manugel)
9 according to Tester and Karkalas (1999). The final
10 starch to non-starch polysaccharide (NSP) ratio was
11 5.7:1 or 19:1. The proportion of the soluble starch
12 to native starch varied according to the proportion
13 of native starch used for the two conditions but was
14 the same for both non-starch polysaccharide
15 conditions and simply serves as a comparison.
16

17 Under clinical supervision, individuals suffering
18 from GSD were fed 70g or 63g (depends on the starch
19 to NSP ratio) samples of NSP encapsulated starch
20 dispersed in cold semi-skimmed milk. The amount of
21 blood glucose and lactate were monitored and are
22 presented in Figures 7 and 8.
23

24 These data show that, although the amount of starch
25 modifies the extent of glucose release as expected,
26 the alginate or pectin components do not stretch out
27 the release profile much beyond 5 hours (300
28 minutes). Hence, the presence of a non-starch
29 polysaccharide 'raft' or food matrix is not enough
30 in itself to slow the rate of starch hydrolysis
31 accordingly (whether native or soluble). The blood
32 lactate response reflects the blood glucose where

1 alginate appears to reduce lactate production more
2 markedly than pectin (since it restricts hydrolysis
3 more).

4

5 **Example 5: Digestion of native starches in the**
6 **presence of lipid**

7

8 Starch (Amioca Powder T, National Starch) with or
9 without addition of soluble starch (Crystal Tex 626,
10 National Starch) was encapsulated in lipid (Revel A,
11 Loders Crocklaan B. V.) as follows. The lipid was
12 dissolved in the minimal amount of ethanol possible
13 to dissolve the starch. The starch was then
14 thoroughly mixed with the ethanol solution until
15 homogeneous. The starch was laid on a tray and air
16 at 35°C was allowed to flow over the
17 ethanol/lipid/starch system (in a fume cupboard)
18 until the ethanol had all evaporated from the
19 system. The final starch to lipid ratio was 9:1.
20 When used, the proportion of soluble starch was 10%
21 of the total starch fraction.

22

23 Under clinical supervision, individuals suffering
24 from GSD were fed 66g samples of lipid encapsulated
25 starch dispersed in cold semi-skimmed milk. The
26 amount of blood glucose was monitored and is
27 presented in Figures 9.

28

29 These data show that the lipid restricts the amount
30 of starch digestion at all times (see previous
31 figures for comparison). Overall, this approach is
32 not appropriate for the control of glucose release

1 (extent of hydrolysis) from the starch as the amount
2 released over time and the actual duration is
3 reduced.

4
5 **Example 6: Digestion of hydrothermally treated**
6 **starches.**

7
8 Starch (Amioca Powder T, National Starch) was
9 thermally treated in a sealed container under the
10 following conditions: 20% moisture and 120°C for 16
11 hours. The treated starches were then cooled to room
12 temperature, air-dried and then passed through 300µm
13 sieve.

14
15 Under clinical supervision, individuals suffering
16 from GSD were fed 60g or 90g samples of heat-
17 moisture treated starch dispersed in cold semi-
18 skimmed milk. The amount of blood glucose and
19 lactate were monitored and are presented in Figures
20 10 and 11.

21
22 These data show that:

23
24 (i) Heat moisture treated (HMT) waxy maize starch
25 has a much reduced initial glucose response at
26 60 minutes than native waxy maize starch
27 (Figure 10).

28 (ii) Because of the reduced initial response more
29 can be fed to be within acceptable levels of
30 glucose increase at this time (where a
31 preferred response is $<8\text{mmol l}^{-1}$).

1 (iii) As a consequence of the above, greater
2 amounts could be fed (90g versus 60g) leading
3 to 7.5 hour (450 minutes) profile where the HMT
4 starch can still maintain the blood glucose at
5 $\sim 2.5 \text{ mmol l}^{-1}$.

6 (iv) The glucose response provides an acceptable and
7 desirable lactate response accordingly (Figure
8 11).

9
10 These data are reinforced by the in vitro assay as
11 shown in Figure 12. Here the HMT treatment can be
12 shown to clearly restrict the hydrolysis of the waxy
13 maize starch.

14
15 Hence, the combination of a waxy starch and its heat
16 moisture treatment allows for the formation of a
17 desirable slow release of glucose therapy. The waxy
18 maize starch is potentially more crystalline than
19 normal or high amylose starches in view of the high
20 amylopectin content.

21
22 A particularly preferred type of starch for this
23 purpose is: semi crystalline with, preferably, the
24 highest proportion of crystallinity possible and
25 with amylase accessibility enhanced by the heat
26 moisture processing.

27
28 All documents referred to in this specification are
29 herein incorporated by reference. Various
30 modifications and variations to the described
31 embodiments of the inventions will be apparent to
32 those skilled in the art without departing from the

1 scope and spirit of the invention. Although the
2 invention has been described in connection with
3 specific preferred embodiments, it should be
4 understood that the invention as claimed should not
5 be unduly limited to such specific embodiments.
6 Indeed, various modifications of the described modes
7 of carrying out the invention which are obvious to
8 those skilled in the art are intended to be covered
9 by the present invention.

1 Claims

2

3 1. A method of controlling serum glucose levels in
4 an individual, said method including the step
5 of administering to said individual a
6 therapeutic food composition comprising a waxy
7 starch.

8

9 2. A method of treating or preventing
10 hypoglycaemia in an individual, said method
11 including the step of administering to said
12 patient a therapeutic food composition
13 comprising a waxy starch.

14

15 3. A method of treating an individual susceptible
16 to hypoglycaemic episodes to prevent or
17 decrease night-time hypoglycaemic episode(s),
18 said method including the step of administering
19 to said individual a therapeutic food

20 composition comprising a waxy starch.

21

22 4. The method according to any one of claims 1 to
23 3 wherein said waxy starch is hydrothermally
24 treated starch.

25

26 5. The method according to claim 4, wherein said
27 hydrothermally treated starch is heat moisture
28 treated starch.

29

30 6. A method of controlling serum glucose levels in
31 an individual said method including the step of
32 administering to said individual a therapeutic

- 1 food composition comprising a hydrothermally
2 treated starch.
3
- 4 7. A method of treating or preventing
5 hypoglycaemia in an individual, said method
6 including the step of administering to said
7 patient a therapeutic food composition
8 comprising a hydrothermally treated starch.
9
- 10 8. A method of treating an individual susceptible
11 to hypoglycaemic episodes to prevent or
12 decrease night-time hypoglycaemic episode(s),
13 said method including the step of administering
14 to said individual a therapeutic food
15 composition comprising a hydrothermally treated
16 starch.
17
- 18 9. The method according to any one of claims 6 to
19 8, wherein said hydrothermally treated starch
20 is heat moisture treated starch.
21
- 22 10. The method according to any one of the
23 preceding claims, wherein said individual has
24 glycogen storage disease.
25
- 26 11. The method according to any one of 1 to 9,
27 wherein said individual has Type I or Type II
28 diabetes.
29
- 30 12. The method according to any one of the
31 preceding claims wherein the starch has an

- 1 amylopectin content of at least 80%.
- 2
- 3 13. The method according to any one of the
- 4 preceding claims, wherein the starch is waxy
- 5 maize starch.
- 6
- 7 14. The method according to any one of the
- 8 preceding claims wherein said therapeutic food
- 9 composition comprises per unit sufficient
- 10 starch to maintain blood glucose concentration
- 11 of greater than 3.0 mmol l^{-1} at 300 min post
- 12 administration.
- 13
- 14 15. The method according to claim 10, wherein said,
- 15 therapeutic food composition comprises per unit
- 16 sufficient starch to maintain blood glucose
- 17 concentration of greater than 2.25 mmol l^{-1} at
- 18 450 min post administration.
- 19
- 20 16. The method according to any one of the
- 21 preceding claims wherein said therapeutic food
- 22 composition comprises per unit dose greater
- 23 than 50 g of starch.
- 24
- 25 17. Use of a starch in the preparation of a
- 26 therapeutic foodstuff for the treatment of
- 27 hypoglycaemia, wherein said starch is waxy
- 28 and/or hydrothermally treated starch.
- 29
- 30 18. Use of a starch in the preparation of a
- 31 therapeutic foodstuff for the treatment or
- 32 prevention of nighttime hypoglycaemic episode,

- 1 wherein said starch is waxy and/or
2 hydrothermally treated starch.
3
- 4 19. The use according to claim 17 or claim 18,
5 wherein said starch is heat moisture treated
6 starch.
7
- 8 20. The use according to any one of claims 17 to 19
9 wherein said individual has glycogen storage
10 disease.
11
- 12 21. The use according to any one of claims 17 to
13 19, wherein said individual has Type I or Type
14 II diabetes.
15
- 16 22. The use according to any one of claims 17 to 21
17 wherein the semi-crystalline starch is a "waxy
18 starch".
19
- 20 23. The use according to any one of claims 17 to 22
21 wherein the semi-crystalline starch has an
22 amylopectin content of at least 70%, preferably
23 at least 80%.
24
- 25 24. The use according to any one of claims 17 to
26 23, wherein the semi-crystalline starch is waxy
27 maize starch.
28
- 29 25. The use according to any one of claims 17 to 24
30 wherein said therapeutic food composition
31 comprises per unit sufficient starch to
32 maintain blood glucose concentration of greater

1 than 3.0 mmol l⁻¹ at 300 min post
2 administration.

3

4 26. The use according to claim 25, wherein said
5 therapeutic food composition comprises per unit
6 sufficient semi-crystalline starch to maintain
7 blood glucose concentration of greater than
8 2.25 mmol l⁻¹ at 450 min post administration.

9

10 27. The use according to any one of claims 17 to 26
11 wherein said therapeutic food composition
12 comprises per unit dose greater than 50 g of
13 semi-crystalline starch.

14

15 28. A therapeutic food kit, said food kit
16 comprising:
17 a) a therapeutic food composition as defined in
18 any one of claims 1 to 16; and
19 b) instructions for ingesting said therapeutic
20 food composition.

21

Glycogen Synthesis (Glucose Storage)

Branched glucan (α -(1-4) and (α -(1-6) bonds) formed from glucose and stored as spherical granules (10-40 nm in diameter)

- Promoted by insulin

a. Linear glycogen chain synthesis – formation of G6P from glucose

Glucose

ATP \downarrow Glucokinase

Glucose-6-phosphate (G6P) + ADP

b. Linear glycogen chain synthesis – formation of G1P from G6P

Glucose-6-phosphate (G6P)

\downarrow Phosphoglucomutase

Glucose-1-phosphate (G1P)

c. Linear glycogen chain synthesis – formation of UDP

Glucose-1-phosphate (G1P)

Uridine triphosphate (UTP) \downarrow UDP-glucose pyrophosphorylase

Uridine diphosphate glucose (UDPG) + PP_i

d. Linear glycogen chain synthesis – formation of linear chains

UDPG

Glycogen_n \downarrow Glycogen synthetase

Glycogen_{n+1} + UDP

e. Introduction of α -(1-6) glycogen branches

Linear Glycogen

\downarrow Branching enzyme

Branches and hence branched glycogen

Figure 1 (P+1)

Glycogen Hydrolysis and Glucose Formation

- Promoted by adrenaline (especially muscle)
- Promoted by glucagon (especially liver)

f. Linear glycogen chain hydrolysis

Linear α -(1-4) Glycogen Residues

$+P_i \downarrow$ Glycogen phosphorylase

Glycogen_{n-1} + Glucose -1-phosphate (G1P)
[glucose cleaved from non-reducing end]

g. Conversion of G1P to G6P

Glucose-1-phosphate (G1P)

\downarrow Phosphoglucomutase

Glucose-6-phosphate (G6P)

h. Conversion of G6P to glucose

Glucose-6-phosphate (G6P)

\downarrow Glucose-6-phosphatase

Glucose + P_i

i. Glycogen branch point hydrolysis

Branched α -(1-6) Glycogen Residues

\downarrow Transferase/ debranching enzyme

Linear Glycogen from transferase activity from α -(1-6) bond

+

Glucose from branch residue (debranching/glucosidase activity)

Note: Blood glucose is maintained at about $\sim 4.5 \text{ mmol l}^{-1}$ in man.

Figure 1. Glucose metabolism

(Fig 2)

Figure 2: Comparison of the hydrolysis profile of native starches using the Karkalas *et al* (1992) procedure.

Figure 3: Blood glucose level after consumption of native starches

Figure 4: Comparison of the blood lactate level after consumption of native starches

Figure 5: Comparison of blood glucose after consumption of two native starches (wheat and waxy maize) with added pregelatinised (maize) starch.

Figure 6: Comparison of the blood lactate level after consumption of two native starches (wheat and waxy maize) with added pregelatinised (maize) starch

Figure 7: Comparison of blood glucose after consumption starch (native waxy maize and soluble) encapsulated with pectin or alginate.

Figure 8: Comparison of blood lactate after consumption of starch (native waxy maize and soluble) encapsulated with pectin or alginate

Figure 9: Comparison of blood glucose after consumption of starch (native waxy maize, soluble) encapsulated with lipid

Figure 10: Comparison of blood glucose after consumption of heat-moisture treated waxy maize starch, waxy maize and normal maize starch.

Figure 11: Comparison of blood lactate after consumption of waxy maize, normal maize and heat-moisture treated waxy maize starches.

Figure 12: Comparison of digestibility of native and heat-moisture treated waxy maize starches
